ABSTRACT

Background and objectives: Diagnosis and treatment of urinary tract infection (UTI) in children before kidney damage is necessary. The purpose of this study was to compare efficacy of co-trimoxazole and cephalexin in the prevention of recurrent UTI in children.

Methods: The study was performed on 100 children aged three months to 14 years who were referred to the Taleghani Pediatric Hospital in Gorgan (Iran) during 2016. The subjects had a history of UTI and required antibiotic prophylaxis to prevent UTI. They were divided into two groups of co-trimoxazole and cephalexin. Data were analyzed using SPSS (version 18) and at significance level of 0.05.

Results: Recurrent UTI was observed in eight children (16.0%) taking cephalexin and in six children (12.0%) receiving co-trimoxazole (p=0.56). Urine culture examination revealed Escherichia coli as the causative agent of UTI in six cases (75 %) receiving cephalexin and in five cases (83.3%) receiving co-trimoxazole (p=0.70). It should be noted that unilateral moderate hydronephrosis was the most frequent anomaly (n=26) in the study groups.

Conclusion: According to the results of the present study, both cephalexin and co-trimoxazole have similar efficacy in the prevention of UTI among children.

INTRODUCTION

Most children with urinary tract infection (UTI) have nonspecific or atypical symptoms and may present with diarrhea, vomiting, etc. In children with fever of unknown origin, a urine culture should be performed to rule out UTI. In a study, about 80% of infants with UTI who had a positive urine culture had a fever of unknown origin (1). Although factors, such as viruses, fungi and parasites are capable of causing UTIs, clinically important infections are usually caused by bacteria. The most common causes of UTI in children are Escherichia coli and Klebsiella pneumoniae from the Enterobacteriaceae family of bacteria. These bacteria can infect the urinary tract in ascending urethra, but bloodstream infections can also occur in rare cases. In addition, UTI may involve the bladder or the upper parts of the urinary tract, such as the urethra, the urinary collecting system and the kidney parenchyma (pyelonephritis). Increased occurrence of UTI is a complex process associated with host genetic and anatomical characteristics as well as invasion, virulence and bacterial locomotor properties of the pathogen (2).

In female students, the recurrence rate of UTI was estimated to be 40% within one year after the primary infection, while it was reported to be 30% among male students (3). There are two types of recurrences: relapse and reinfection. Relapse is defined as recurrent infection with the same strain, while reinfection means recurrent infection with a different strain (4). Recurrent UTI is often referred to as two or more UTIs in six months. Recurrent UTI risk factors include vesicoureteral reflux, urinary tract disorders, neurogenic bladder, urinary dysfunction, constipation, immunodeficiency, hypercalciuria and urinary stone. Antibiotic prophylaxis is recommended for cases at high risk of kidney damage or urosepsis, including a high degree of reflux, urinary tract obstruction, recurrent symptomatic UTI, bladder dysfunction and urinary dysfunction (5).

Children with vesicoureteral reflux (VUR) are at greater risk for recurrent UTI compared to those without VUR, and the reflux grade III and IV are associated with the highest risk. Another important factor in VUR is recurrent bladder dysfunction. Prevention of recurrent UTI in these patients involves antibiotic prophylaxis and treatment of bladder dysfunction (6). Therefore, long-term antibiotic prophylaxis should be considered in high-risk children to prevent kidney damage. Different drugs such as co-trimoxazole (trimethoprim-sulfamethoxazole), nitrofurantoin, nalidixic acid, ciprofloxacin and cephalexin have been recommended as prophylaxis to prevent UTI in children (7). Routine use of nitrofurantoin in bacterial eradication has not been effective in patients with chronic neurogenic bladder (8). Gastrointestinal intolerance is the most common side effect of nitrofurantoin (9). Nalidixic acid is one of the most important causes of pseudotumor cerebri in infants (10). Increasing resistance to antibiotics makes it difficult to treat the patients. More than 50% of E. coli strains are resistant to amoxicillin and ampicillin. Resistance to co-trimoxazole and cephalosporins is also increasing (11, 12). The rate of microbial resistance in each region may vary over the years (13). In this study, we compare the efficacy of cotrimoxazole and cephalexin in preventing recurrence of UTI in children referred to the Taleghani Hospital in Gorgan, north of Iran.

MATERIAL AND METHODS

This cohort study was conducted on children aged three months to 14 years old who were referred to the Taleghani Pediatric Hospital with a history of UTI. The study was approved by the ethics committee of Golestan University of Medical Sciences (approval code: IR.GOUMS.REC.1398.175). Based on the study by Ghane Sharbaf et al. (14) and given the recurrence rate of 21.1% in the co-
trimoxazole group and 48% in the nalidixic acid group, the sample size of 50 was considered for each group. Data were collected through interviews, examinations and checklists. Complete urine test and culture were performed to confirm UTI. For all children, kidney and urinary tract ultrasonography were performed by an experienced sonographer, and also the standard voiding cystourethrogram (VCUG) or radionuclide cystogram (RNC) were carried out based on indications, including the presence of pyelonephritis or any abnormality on ultrasonography in the presence of a UTI.

After treatment of acute infection, the subjects were divided into two groups and underwent prophylaxis with either trimethoprim-sulfamethoxazole or cephalixin based on results of the antibiotic susceptibility test. These evaluations were performed more frequently whenever there was suspicion of UTI based on the recurrence of symptoms. Recurrence was considered as a new UTI with the same or a different strain of pathogens. During the study, all demographic data including age, gender as well as information on antibiotic prophylaxis, underlying diseases and urinary anomalies were recorded. The subjects included children who were at risk for recurrent UTI and on prophylaxis with co-trimoxazole or cephalixin including those with grade 3 or higher urinary tract reflux, bladder dysfunction, urinary tract obstruction, recurrent UTIs (at least two UTIs within six months) as well as those who developed UTI while taking the prophylactic drugs. Exclusion criteria were failure to parental follow-up, drug intolerance and stopping the medication by the patient.

Data were analyzed using SPSS (version 18). The Shapiro-Wilk test was used to check normal distribution of data. The chi-square test, t-test and Mann-Whitney test were used to analyze quantitative and qualitative variables. A p-value of less than 0.05 was considered significant.

RESULTS

In this study, 100 children (48 male) aged three months to 14 years with a history of UTI who needed antibiotic prophylaxis to prevent UTI were enrolled. The subjects were equally divided into a cephalixin and a co-trimoxazole group. To further assess the effects of the drugs, children were qualitatively divided into two groups of less than 4 and older than 5 years old. The mean age of children was 44.5 ± 43.75 months, ranging from three months to 13 years (156 months). The subjects were matched in terms of age and gender (Table 1).

Overall, the recurrence rate of UTI was 14% among the subjects. Moreover, UTI recurrence rate was found to be 16% in children receiving cephalixin and 12% in children receiving co-trimoxazole. The difference between the two groups was not statistically significant (p=0.56).
When comparing the time of UTI recurrence between the two groups, it was found that the mean recurrence time was 1.12 ± 1.88 months in the children receiving cephalexin and 1.21 ± 2.33 months in the children receiving co-trimoxazole (p=0.49). In the urine culture analysis, out of 14 UTI recurrences, 11 cases (78.6%) were caused by E. coli and three cases (21.4%) were caused by Pseudomonas spp. In the co-trimoxazole group, one case (16.7%) of Pseudomonas spp. and five cases (83.3%) of E. coli infections were observed in the cultured samples. However, there was no significant difference between the two groups in terms of the causative bacteria (p=0.70). Moreover, there was no significant difference between the two groups in ultrasonography results (p=0.16) (Table 2). It should be noted that unilateral moderate hydronephrosis was the most frequent finding (n=26 cases).

In the cephalexin group, 17 cases (34.0%) had normal RNC or VCUG and 13 cases (26.0%) had grade IV vesicoureteral reflux. In the co-trimoxazole group, 22 cases (44.0%) had normal RNC or VCUG results and 10 cases (20.0%) had grade IV. However, the difference between the two groups was not statistically significant (p=0.47) (Figure 1).

The findings indicated that 14 children (23%) with abnormal RNC or VCUG had a UTI recurrence, which was statistically significant (p=0.001) (Table 3). Also, the recurrence rate of UTI based on reflux grade showed that nine children (39.1%) with grade IV had a recurrence of infection, which was statistically significant (p<0.001) (Table 3).

DISCUSSION

As mentioned earlier, UTI is one of the most common bacterial infections in children. These infections affect the kidney, ureter or bladder (15). Given the limitations of studies on the use of appropriate prophylactic medication in children with recurrent UTI, and also the regional differences in the antibiotic sensitivity patterns, this study was performed to compare the efficacy of co-trimoxazole and cephalaxin in the prevention of recurrent UTI in children aged three months to 14 years. The main finding of the present study was that the incidence of recurrence was not considerably different between the co-trimoxazole and cephalaxin groups. In other words, the two drugs acted similarly in preventing UTI recurrence in children. In a similar study by Amirhassani et al., the efficacy of nalidixic acid and co-trimoxazole was not significantly different (16). However, a study by Ghanesharbat et al. showed that prophylaxis with co-trimoxazole is preferable over nalixic acid in children with UTI (14). The risk of UTI recurrence in children is 30% after the first infection and 70% after the third infection; therefore, it is necessary to prevent long-term antibiotic prophylaxis in high-risk children (17). Amini et al. found that the rate of resistance to co-trimoxazole and cephalaxin was approximately equal (18). One of the strengths of the present study was to compare the time of UTI recurrence in both groups. The duration of recurrence was two months in children taking co-trimoxazole and one month in children under cephalaxin therapy. Furthermore, the prevalence of recurrent UTI was 14% in the studied children. A study by Dodge et al. reported a recurrence rate of approximately 21% for UTI (19). Sorkhi et al. reported a recurrence rate of 22.6% for UTI among children (20). In another study, Gillenwater et al. reported that about 25% of people with UTI relapsed (21). The rate of recurrence in these studies is higher than the rate observed in our study. This may be due to the difference in sample size, voiding dysfunction and the reflux grades, which may affect the results.

In the present study, E. coli followed by Pseudomonas spp. were identified as the most common causes of UTI. However, there was no significant difference between the two groups in terms of causative agent of UTI recurrence. It is known that UTIs are mainly caused by gram-negative bacilli and E. coli (22). Previous studies also reported E. coli as the most common isolate from
According to the results of ultrasonography of pediatric urethra, hydronephrosis was the most frequent anomaly in the study groups. In a study conducted by Hemmatyar et al. with a subsequent follow-up, there was no case of urinary reflux on VCUG (25), which is in line with our findings.

UTI is an important cause of progressive scarring, degeneration of kidney structures, renal failure, urinary stones and hypertension in children (26). Therefore, early diagnosis and treatment with proper antibiotics are essential to prevent these complications. In our study, the number of normal cases of RNC or VCUG in children under co-trimoxazole therapy was 1.2 times more than in those on cephalexin, but there was no significant difference between the two groups. Similar to our findings, Neilson stated that 10 to 35% of vesicoureteral reflux cases had underlying malformations (27). Litaka et al. also found that 21% of children with permanent bacteriuria had anomalies (28).

CONCLUSION
According to the results of the present study, both cephalexin and co-trimoxazole have similar efficacy in preventing the recurrence of UTI in children. Either of these two antibiotics could be used on the basis of patient tolerance and the antibiotic susceptibility pattern.
